The entire function is automated and user-friendly, and you don't have to understand it before. The present invention relates to a dispenser for an article, such as a roll of toilet tissue or a roll of paper toweling, having a housing with a chamber, a flap for opening and closing an aperture in the chamber, and a pusher device for moving the flap from an open position to a closed position. More particularly, the present invention relates to a dispenser in which the pusher device includes a motor that is coupled to an end of the housing opposite the chamber and has a driving shaft and a hub having a plurality of threaded holes, and a plurality of pinions engaging the threaded holes. Dispensers for articles, such as a roll of toilet tissue, are well known. Typically, the dispensers include a housing having a chamber for storing the article. An opening is provided in the housing to permit access to the article in the chamber. A flap is hinged to the housing to selectively cover the opening. The flap is biased by a spring to a closed position to seal the opening. Many dispensers are manual in that a user must manually move the flap into a closed position. These manually operated dispensers have proven to be desirable because they are convenient for users. However, they also have disadvantages in that they can be difficult to use in situations where the user needs both hands. There have also been dispensers that include a motor for moving the flap from a closed position to an open position. These motors have proved to be desirable because they allow a user to operate the dispenser with one hand. However, they also have disadvantages in that they are often complex and expensive.
