Clonal evolution and chimerism in myelodysplastic syndromes. Chromosomal changes during the course of the disease in patients with myelodysplastic syndromes (MDSs) are well established. However, it is more difficult to define the mechanisms involved in clonal evolution of these disorders. Whether and to what extent a single, or a group of, genetic abnormalities are required for the onset and progression of these diseases has still to be determined. The existence of complex chromosomal rearrangements (CMRs) in patients with MDS has pointed towards the role of CMRs in the clonal evolution of this disease. Some of these rearrangements seem to be related to the initiation of the disease and are associated with a poor prognosis. However, mechanisms regulating the selection of these rearrangements and the precise order of events in the evolution of the disease are not well understood. The presence of abnormal clones and subclones of cells with similar genetic abnormalities may be responsible for the heterogeneity of clinical manifestations in patients with MDSs and an increased tendency to relapse. Gene expression profiling of MDSs may help in understanding the mechanisms involved in the progression of MDS.
